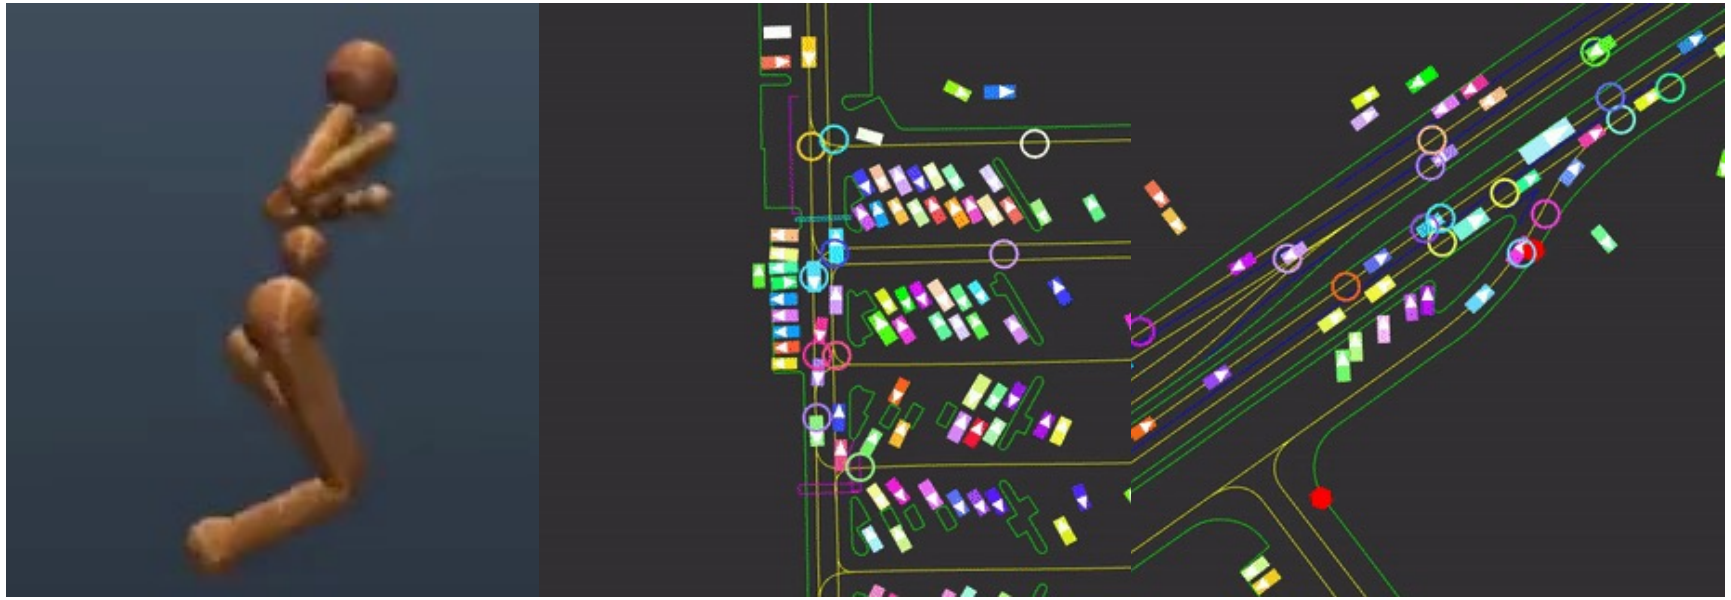
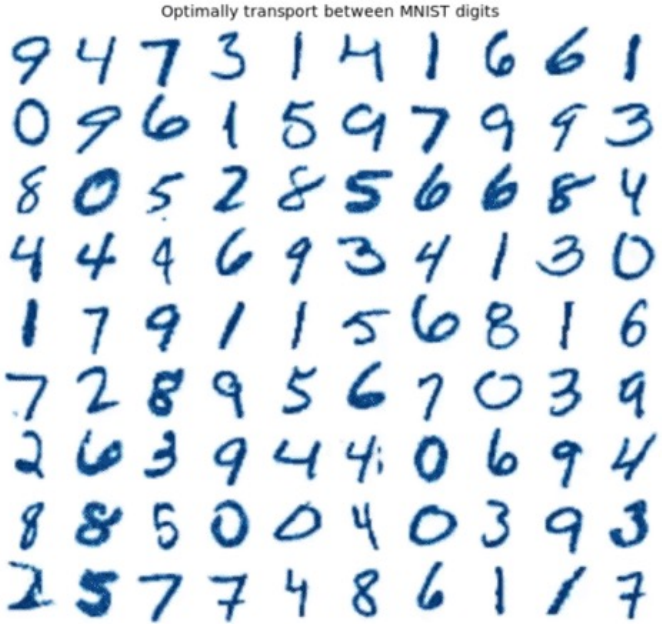
Optimization is a powerful modeling tool

Continuous optimization expresses many **non-trivial operations**

Control, reinforcement learning, robotics, geometry (projections), variational inference, finance (portfolio optimization), sparse coding, meta-learning, deep equilibrium networks, optimal transport, game and market equilibrium





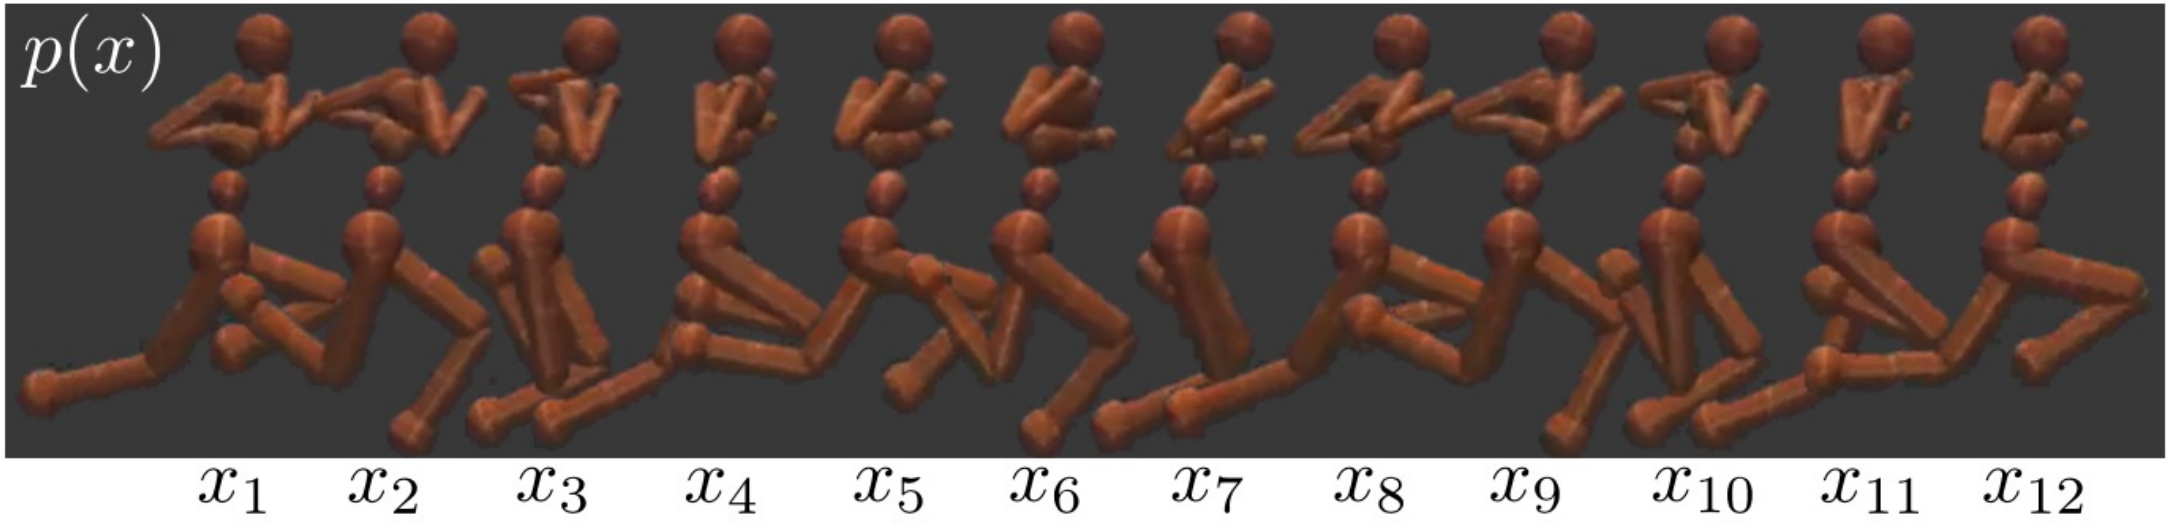
Repeatedly solving optimization problems

Optimization problems often **do not live in isolation** and are often **repeatedly solved** in deployment

$$y^\star(x) \in \operatorname{argmin}_y f(y; x)$$

Optimal solution | Optimization variable | Objective | Context

In control, x is the system state, y is the action, $f(y; x)$ is a cost, and $y^\star(x)$ is an optimal action



Difficulty: optimization is computationally expensive

Sometimes solving just **once** may be difficult
Exasperated when **repeatedly solving** during deployment

Insight: optimal solutions share structure

Optimization problems **share structure** and don't live in isolation

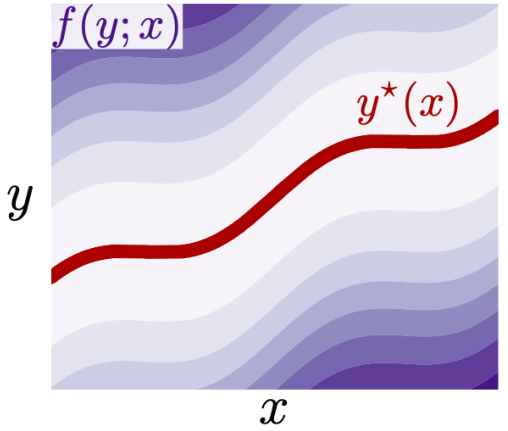
Solution: amortized optimization

Use **machine learning** to uncover the shared structure
Create **learning-augmented** versions of classical optimization solvers
Far surpasses average or worst-case convergence rates

Amortized optimization foundations

This talk: Explore foundations and applications

$$y^\star(x) \in \operatorname*{argmin}_y f(y; x)$$

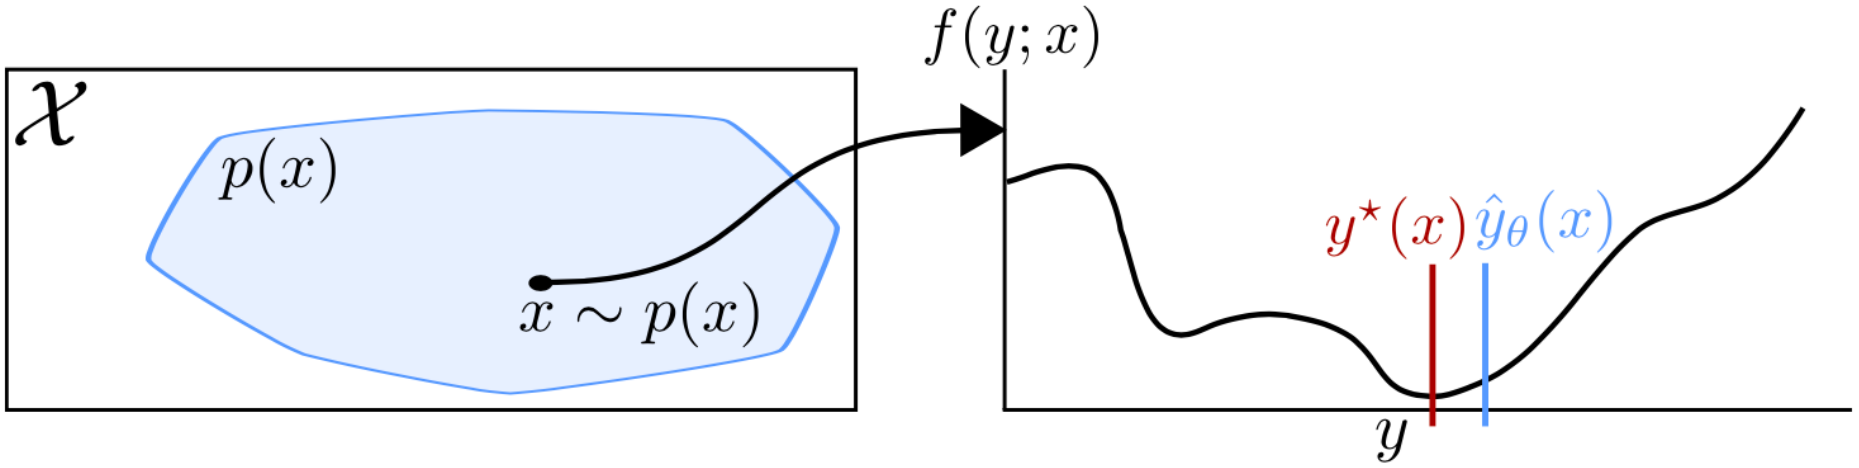


Amortization model $\hat{y}_\theta(x)$ tries to approximate $y^\star(x)$

Example: A neural network mapping from x to the solution

Loss $\mathcal{L}$ measures how well $\hat{y}$ fits $y^\star$ and optimized with $\min_\theta \mathcal{L}(\hat{y}_\theta)$

Example: $\mathcal{L}(\hat{y}_\theta) \coloneqq \mathbb{E}_{p(x)} \|\hat{y}_\theta(x) - y^\star(x)\|_2^2$



Amortized optimization is already ubiquitous

My goal: characterize and **connect** applications previously developed **independently from each other**

§	Application	Objective f	Domain $\mathcal{Y}$	Context Space $\mathcal{X}$	Amortization model $\hat{y}_\theta$	Loss $\mathcal{L}$

Reinforcement learning

Neural Potts Model for protein modeling

Meta optimal transport

Modeling paradigms for $\hat{y}_\theta$

How to best-predict the solution?

Fully-amortized models: Map from the context x to the solution **without** accessing the objective f

Example: Neural network mapping from x to the solution

Most of our applications will focus on these

Semi-amortized models: Internally access the objective f

Example: Gradient-based meta-learning models such as MAML

$$\hat{y}_\theta^0 \rightarrow \hat{y}_\theta^1 \rightarrow \cdots \rightarrow \hat{y}_\theta^K =: \hat{y}_\theta(x)$$

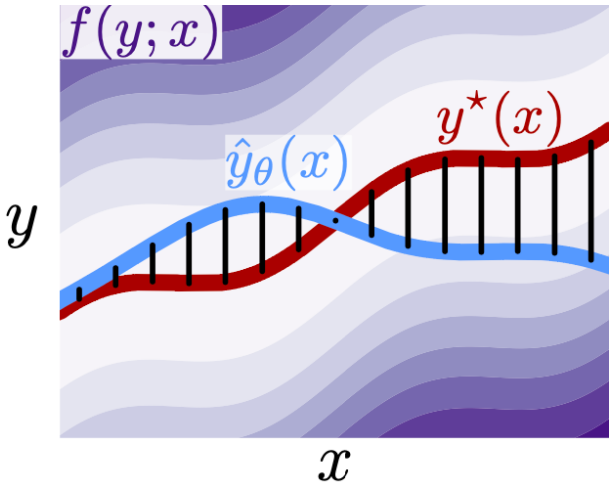
Learning paradigms for $\mathcal{L}$

What should the model $\hat{y}_\theta$ optimize for?

Regression-based

$$\mathcal{L}_{\text{reg}}(\hat{y}_\theta) \coloneqq \mathbb{E}_{p(x)} \|\hat{y}_\theta(x) - y^\star(x)\|_2^2$$

- $-$ Does not consider $f(y; x)$
- $+$ Uses global information with $y^\star(x)$
- $-$ Expensive to compute $y^\star(x)$
- $+$ Does not compute $\nabla_y f(y; x)$
- $-$ Hard to learn non-unique $y^\star(x)$



Objective-based:

$$\mathcal{L}_{\text{obj}}(\hat{y}_\theta) \coloneqq \mathbb{E}_{p(x)} f(\hat{y}_\theta(x); x)$$

- $+$ Uses objective information of $f(y; x)$
- $-$ Can get stuck in local optima of $f(y; x)$
- $+$ Faster, does not require $y^\star(x)$
- $-$ Often requires computing $\nabla_y f(y; x)$
- $+$ Easily learns non-unique $y^\star(x)$

Reinforcement learning

Neural Potts Model for protein modeling

Meta optimal transport

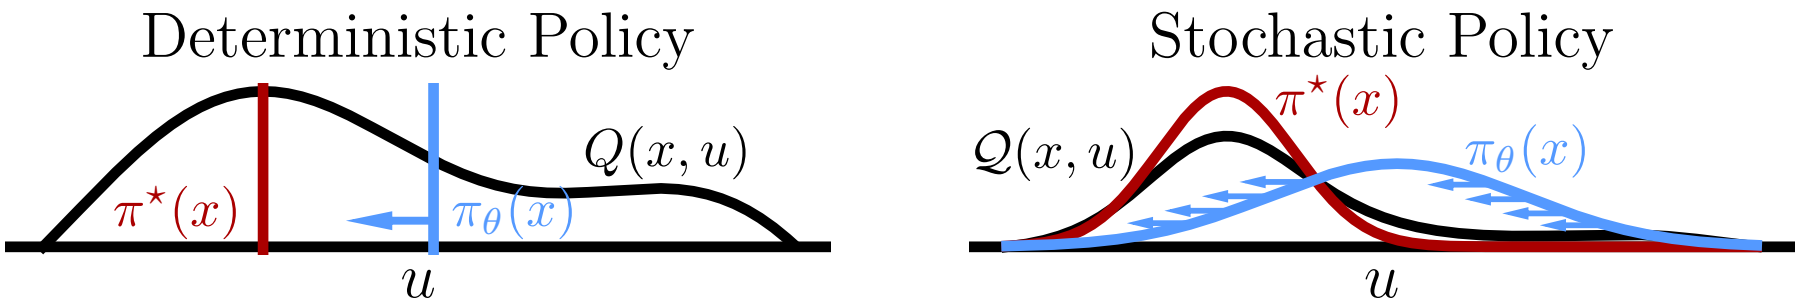
RL policy learning is amortized optimization

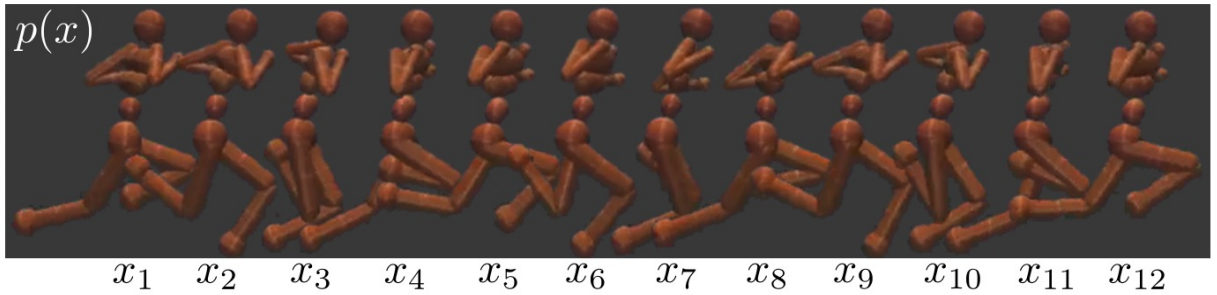
Setup: controlling a **continuous MDP** with a **model-free policy** $\pi_\theta(x)$

Review: Learning a policy with a **value gradient** amortizes over the Q-value:

$$\underset{\theta}{\text{argmax}}\, \mathbb{E}_{p(x)}\, Q(x, \pi_\theta(x))$$

The **amortization perspective** easily enables **expanding beyond this fully-amortized setting**





Semi-amortized policy learning

Iterative Amortized Policy Optimization

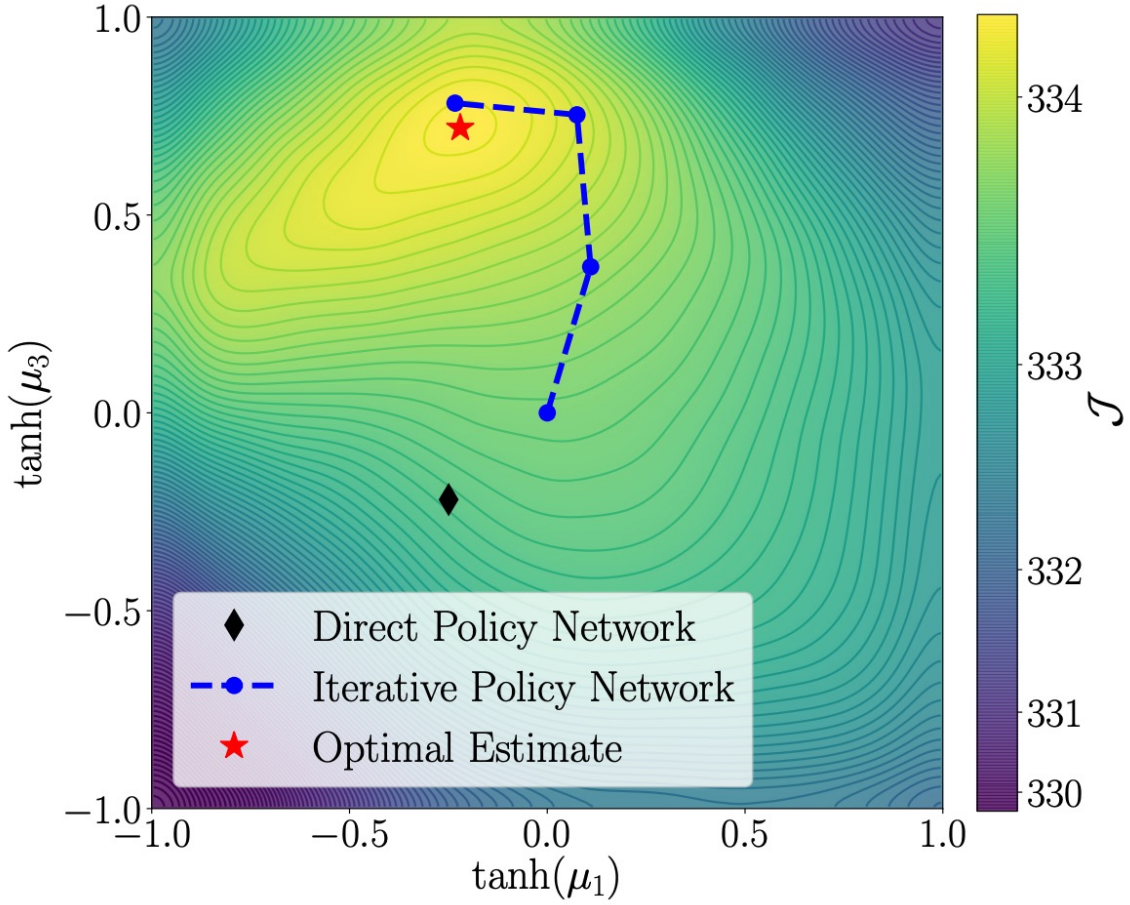
Abstract

Policy networks are a central feature of deep reinforcement learning (RL) algorithms for continuous control, enabling the estimation and sampling of high-value actions. From the variational inference perspective on RL, policy networks, when used with entropy or KL regularization, are a form of *amortized optimization*, optimizing network parameters rather than the policy distributions directly. However, *direct* amortized mappings can yield suboptimal policy estimates and restricted distributions, limiting performance and exploration. Given this perspective, we consider the more flexible class of *iterative* amortized optimizers. We demonstrate that the resulting technique, iterative amortized policy optimization, yields performance improvements over direct amortization on benchmark continuous control tasks. Accompanying code: `github.com/joelouismarino/variational_rl`.



Decision-time fine-tuning and planning

Rely on **standard policy methods** such as PPO to **amortize the solution to a game**
Fine-tune at decision time by **constraining to the initial state** and **continuing policy optimization**

Scalable Online Planning via Reinforcement Learning Fine-Tuning

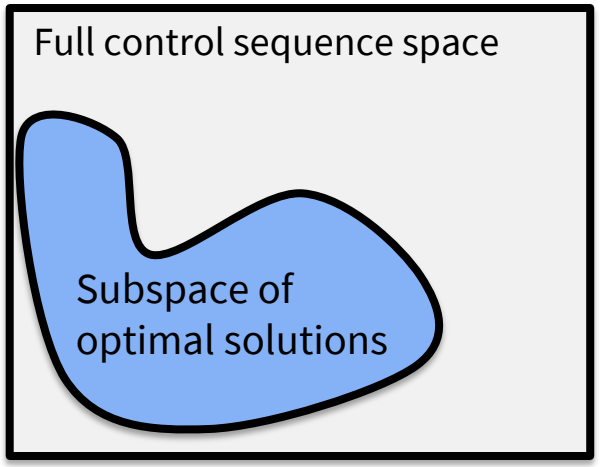
Amortization via learning latent subspaces

Amortize the problem by **learning a latent subspace** of optimal solutions
Only search over optimal solutions rather than the entire space

$$x^\star_{1:T}, u^\star_{1:T} \in \underset{x_{1:T}, u_{1:T}}{\operatorname{argmin}} \sum_t \underbrace{C_\theta(x_t, u_t)}_{\text{cost}} \text{ s.t. } \underbrace{x_1 = x_{\text{init}}}_{\text{initial state}} \quad \underbrace{x_{t+1} = f_\theta(x_t, u_t)}_{\text{dynamics}} \quad \underbrace{u_t \in \mathcal{U}}_{\text{constraints}}$$

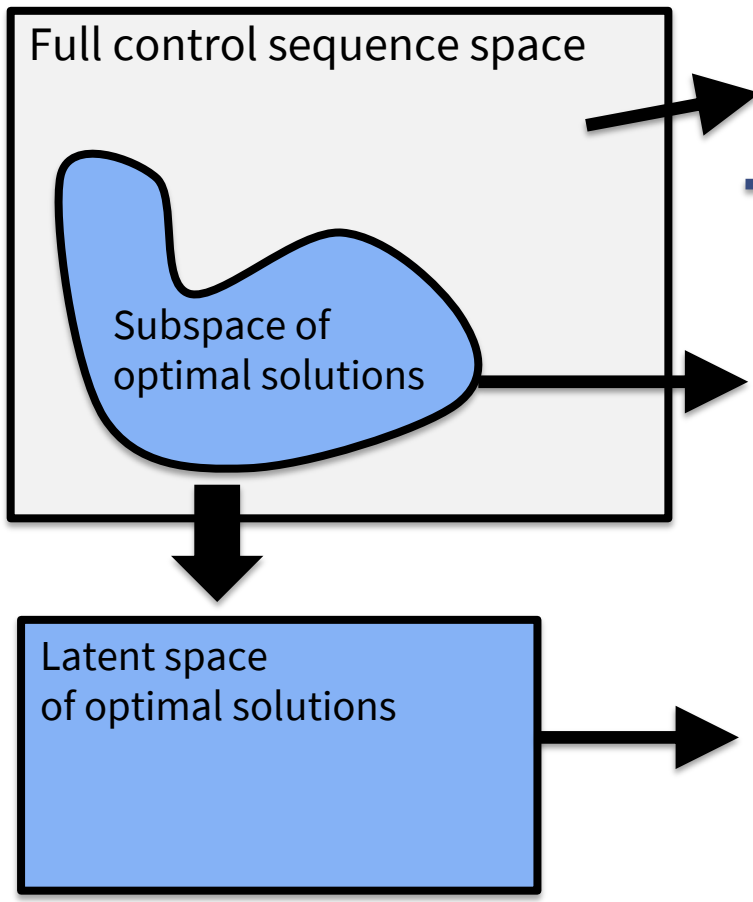


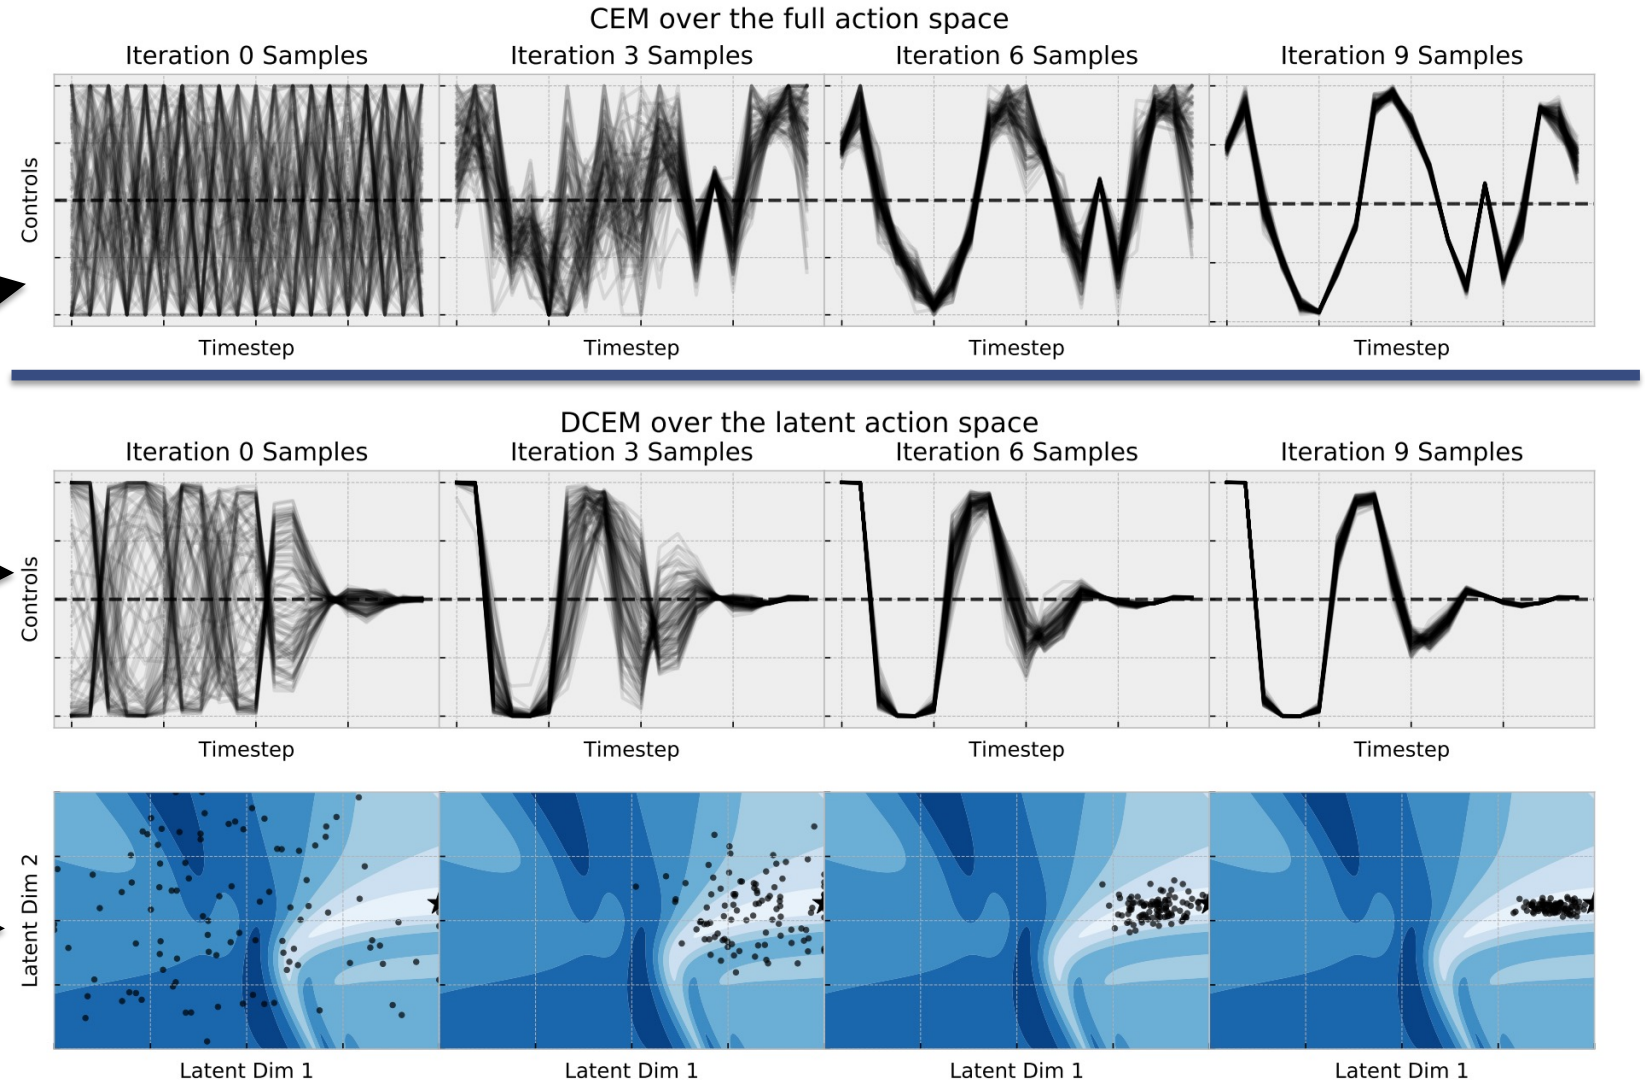
Cartpole videos

Optimal controls over time — force on the cartpole

Amortization via learning latent subspaces

$$u^\star = \underset{u \in [0,1]^N}{\operatorname{argmin}} \; f(u)$$

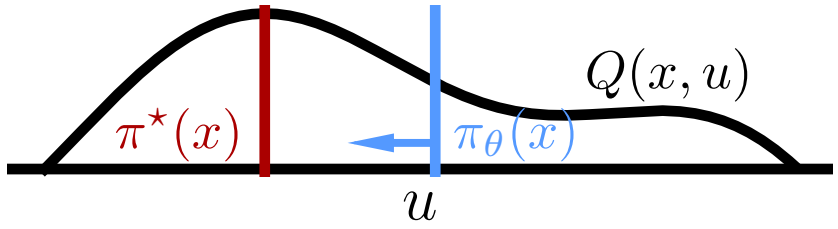




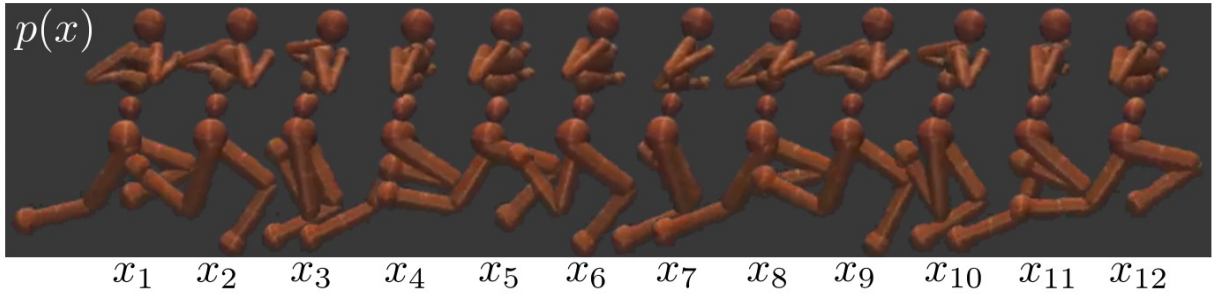
VAE amortization is conceptually the same as RL

Value gradient amortization in RL

$$\underset{\theta}{\text{argmax}}\, \mathbb{E}_{p(x)}\, Q(x, \pi_\theta(x))$$

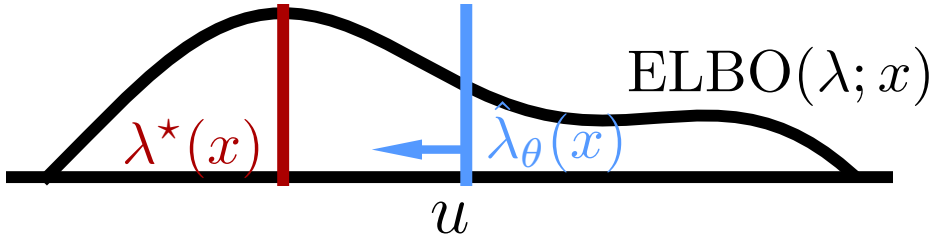


x: states from system



VAE posterior amortization

$$\underset{\theta}{\text{argmax}}\, \mathbb{E}_{p(x)}\, \text{ELBO}(\hat{\lambda}_\theta(x); x)$$



x: images from dataset

This talk: amortized optimization

Design decisions

Modeling paradigms for $\hat{y}_\theta$ (fully-amortized and semi-amortized models)

Learning paradigms for $\mathcal{L}$ (objective-based and regression-based)

Selected applications

Reinforcement learning

Neural Potts Model for protein modeling

Meta optimal transport

Neural Potts Model

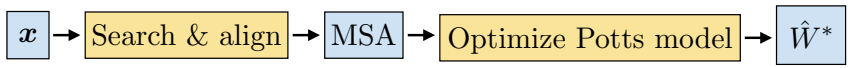
Potts model: A **Gibbs distribution** over a **protein sequence** x:

$$-E(x) \stackrel{\text{def}}{=} \sum_i h_i(x_i) + \sum_{ij} J_{ij}(x_i, x_j)$$

parameterized by $W = \{h, J\}$

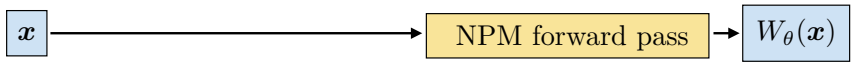
Standard Potts (baseline) ■

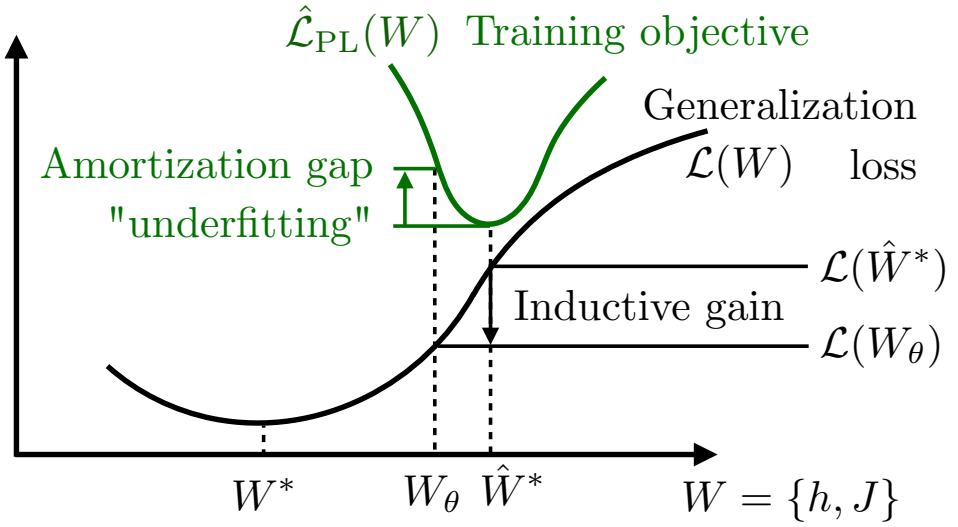
Independently optimize the likelihood for every sequence



Neural Potts ■

Amortize and jointly optimize for all sequences at once





Contact predictions

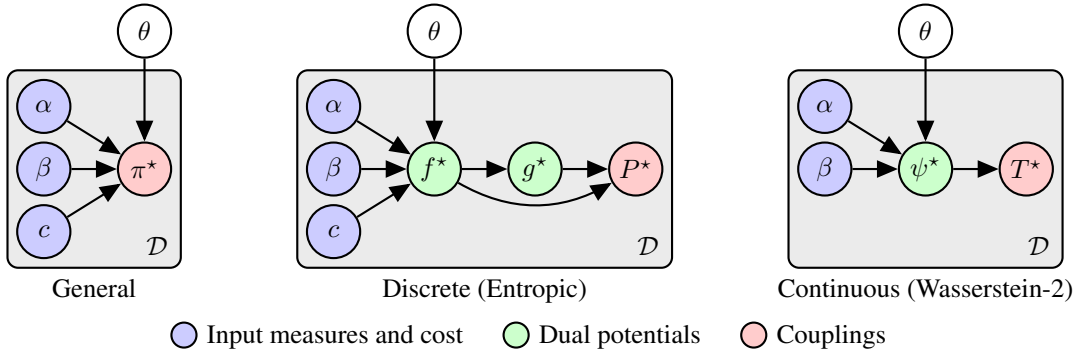
Design decisions

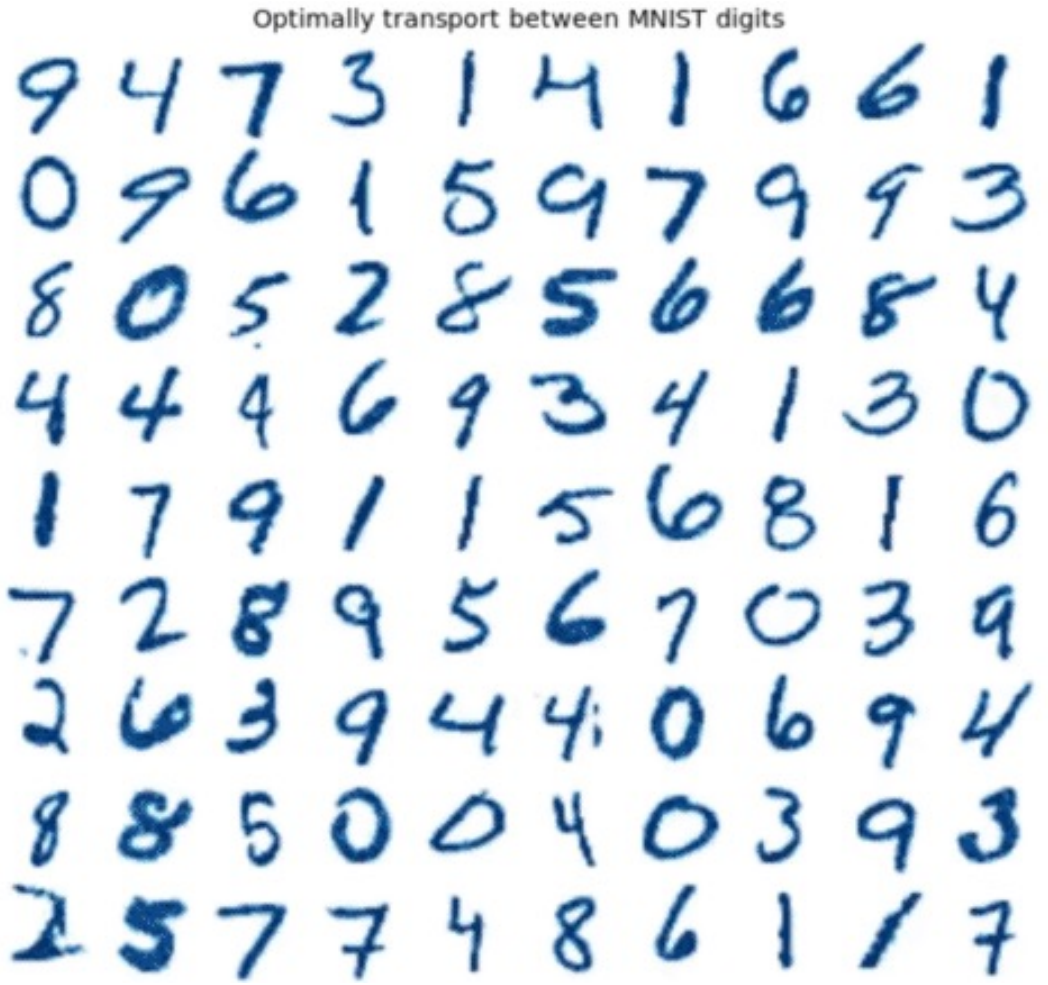
- **Modeling** paradigms for $\hat{y}_\theta$ (fully-amortized and semi-amortized models)
- **Learning** paradigms for $\mathcal{L}$ (objective-based and regression-based)

Selected applications

- Reinforcement learning
- Neural Potts Model for protein modeling
- Meta optimal transport

Meta Optimal Transport





Goal: optimally transport mass between measures α to β

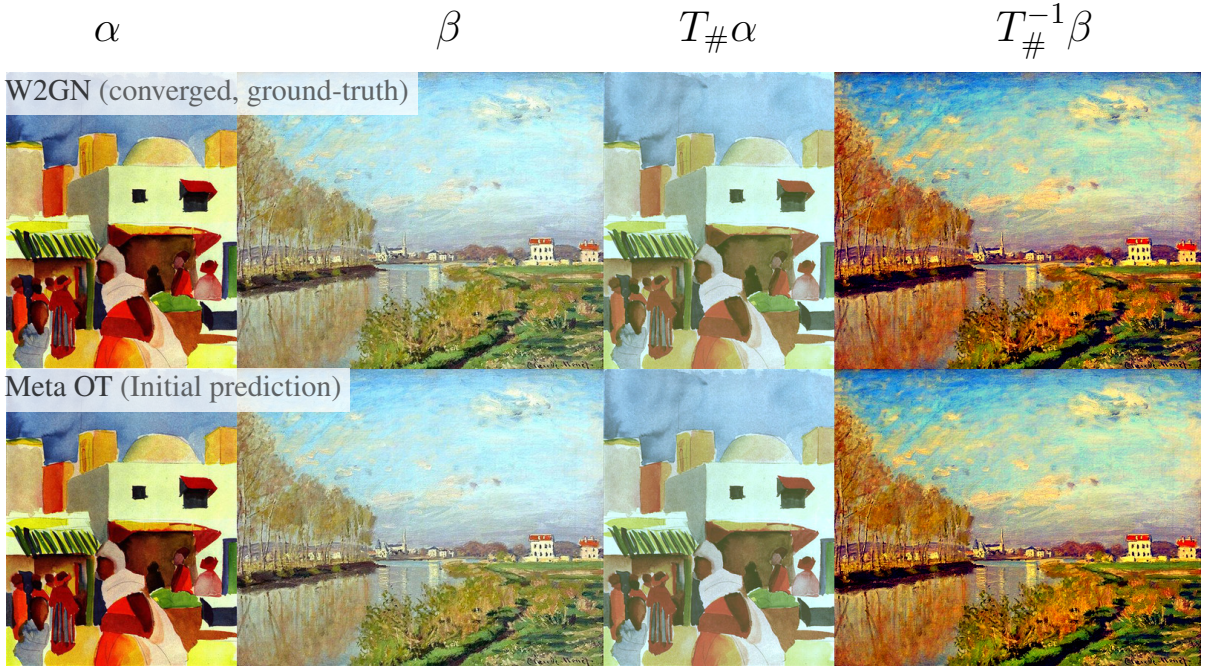
$$\pi^\star(\alpha, \beta, c) \in \underset{\pi \in \mathcal{U}(\alpha,\beta)}{\operatorname{argmin}} \int_{\mathcal{X}\times\mathcal{Y}} c(x,y)\mathrm{d}\pi(x,y)$$

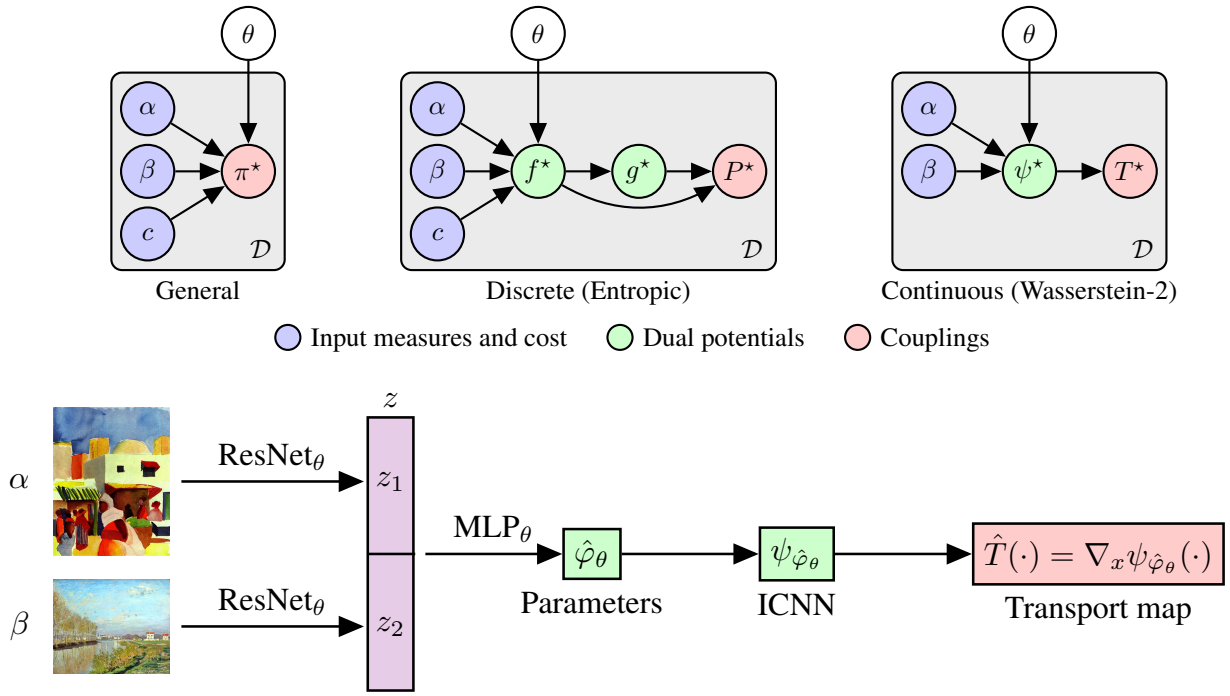
Use **amortization** when **repeatedly coupling measures**
e.g., between pairs of images or physical transport

Often amortize over **unconstrained dual potentials**

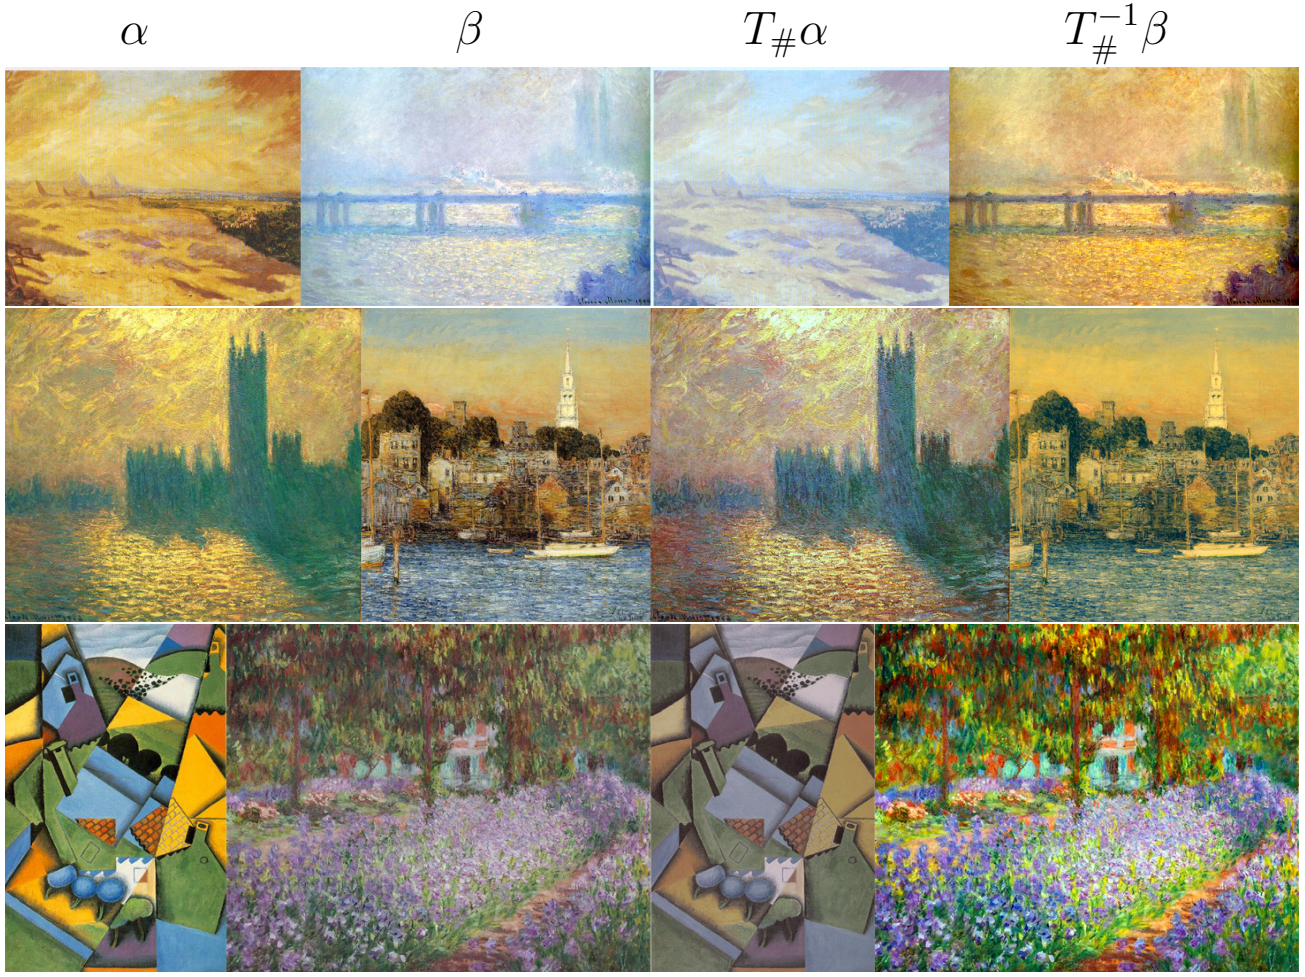
Meta Optimal Transport

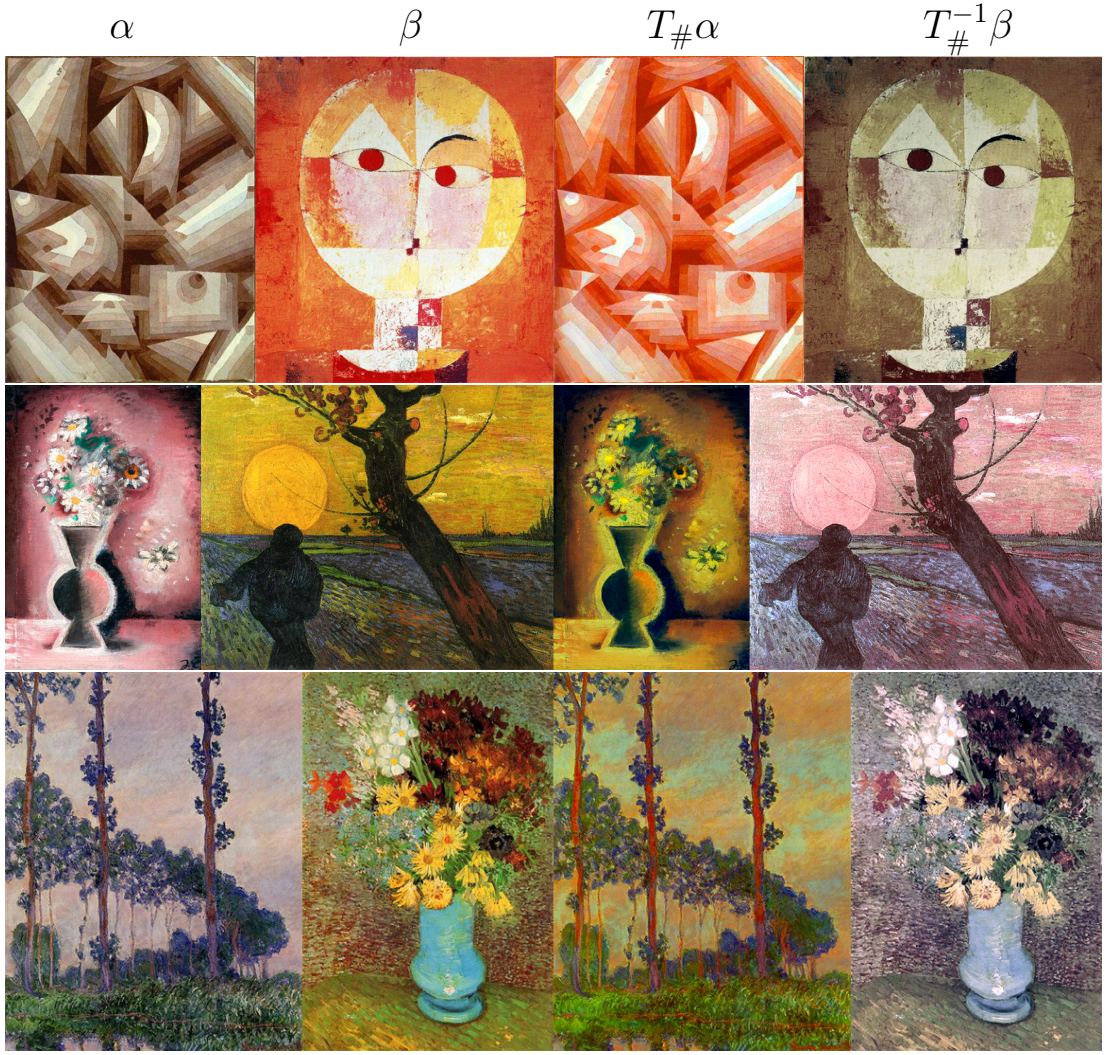
Predict couplings **100x faster** than SOTA solvers that doesn't use learning





More meta color transfer predictions



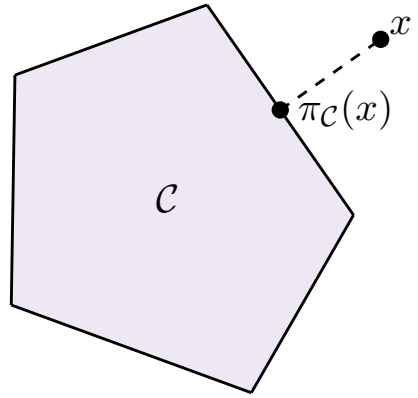


Future directions and limitations

Amortized optimization is established and budding with new methods and applications

Possible to expand far beyond **unconstrained continuous Euclidean optimization** settings:

1. **New applications and settings for semi-amortized modeling**
2. **Constrained domains** (e.g., with differentiable projections)
3. **Discrete optimization settings** (e.g., with differentiable discrete optimization)
4. **Non-Euclidean settings** (e.g., with Riemannian optimization)



Potential limitations:

1. Difficult in **out-of-domain settings** when the contexts significantly change
2. Generally difficult to **ensure stability or convergence**
3. Typically **does not solve previously intractable problems**
4. Can be **difficult to obtain high-accuracy solutions** without fine-tuning/semi-amortization
